Understanding Dilations

Dilations are a type of transformation in geometry that alters the size of a figure without affecting its shape. This transformation is characterized by a center of dilation and a scale factor. The center of dilation is a specific point in the plane from which all points of the figure are expanded or contracted. The scale factor determines how much the figure is enlarged or reduced. A scale factor greater than one indicates an enlargement, while a scale factor between zero and one indicates a reduction.

For example, if a triangle has vertices at coordinates $(1,2)$, $(3,4)$, and $(5,6)$, and the center of dilation is at the origin $(0,0)$ with a scale factor of 2, the new coordinates after dilation would be $(2,4)$, $(6,8)$, and $(10,12)$. Understanding these transformations is critical for solving various geometric problems, particularly in the context of similar figures and proportional relationships.
