Understanding Exponential Functions

Exponential functions are mathematical expressions in which a constant base is raised to a variable exponent. They are typically represented in the form of $f(x) = a \cdot b^x$, where a is a constant, b is the base (a positive real number), and x is the exponent. These functions are characterized by their rapid growth or decay, making them essential for modeling real-world phenomena.

Characteristics of Exponential Functions

Exponential functions exhibit several key characteristics that distinguish them from linear functions:

- **Growth and Decay:** When the base $(b > 1)$, the function represents exponential growth. Conversely, if $(0 < b < 1)$, it illustrates exponential decay.
- **Y-Intercept:** The y-intercept of an exponential function $(f(0))$ is always equal to (a) , which is the initial value.
- **Asymptotic Behavior:** The function approaches the x-axis but never actually touches it, indicating that exponential functions have a horizontal asymptote at $(y = 0)$.
- **Domain and Range:** The domain of exponential functions is all real numbers, while the range is always positive real numbers.
